INTRODUCTION

- Zanubrutinib, a next-generation covalent Bruton tyrosine kinase inhibitor (BTKi), is the only BTKi that demonstrated progression-free survival (PFS) superiority vs ibrutinib (first-generation BTKi) in relapsed or refractory (R/R) chronic lymphocytic leukemia (CLL) in the ALPINE trial[1]
- Acalabrutinib, a second-generation BTKi, showed improved PFS vs rituximab-idelalisib/bendamustine in R/R CLL in the ASCEND trial,[2,3] but PFS noninferiority vs ibrutinib in patients with R/R CLL with chromosome 17p or 11q deletions in the ELEVATE-RR trial[4]
- As no head-to-head clinical trial of zanubrutinib and acalabrutinib in R/R CLL exists, an indirect treatment comparison was performed to evaluate the relative efficacy of these 2 treatments
- The objective of this study was to compare the efficacy of zanubrutinib in ALPINE and acalabrutinib in ASCEND using matching-adjusted indirect comparison (MAIC) methodology

METHODS

- Individual patient-level data (IPD) from ALPINE were matched against the aggregate data from ASCEND[1-3]
- An unanchored MAIC was used due to the lack of a common comparator arm between the ALPINE and ASCEND trials
- Given the timing of the study in relation to the COVID-19 pandemic for ASCEND vs ALPINE, adjustments on ALPINE were made for the impact of COVID-19
- Population adjustment in the base case analysis considered all variables identified as prognostic factors or predictors of treatment effect (**Table 1; Figure 1**)
- Pseudo IPD for PFS and overall survival (OS) in the acalabrutinib arm of ASCEND were reconstructed from the digitized Kaplan-Meier curves reported in the ASCEND publication using the algorithm by Guyot et al[5]
- A weighted Cox proportional hazard model was used to compare investigator-assessed PFS (PFS-INV) and OS and a weighted logistic regression model to compare complete response (CR)

Table 1. Covariates Matched in the Base Case and Sensitivity Analyses

	Main Analysis		Sensitivity Analyses

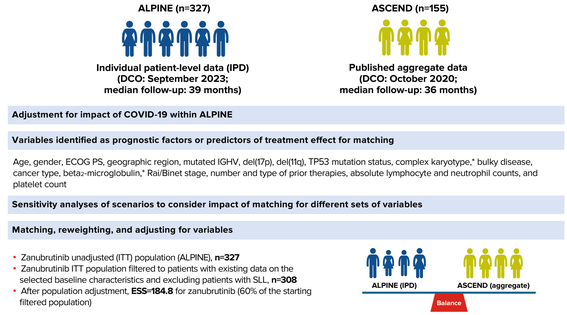
* Covariates not matched in the base case.
Del (11q), chromosome 11q deletion; del (17p), chromosome 17p deletion; ECOG PS, Eastern Cooperative Oncology Group Performance Status; IGHV, immunoglobulin heavy-chain variable; LD, longest diameter.

METHODS

Figure 1. Details of the Overall Methodology



* Covariates not matched in the base case.
DCO, data cut-off; del(11q), chromosome 11q deletion; del(17p), chromosome 17p deletion; ECOG PS, Eastern Cooperative Oncology Group Performance Status; ESS, effective sample size; HR, hazard ratio; IGHV, immunoglobulin heavy-chain variable; ITT, intent-to-treat; OR, odds ratio; SLL, small lymphocytic lymphoma.

RESULTS

Efficacy outcomes

- PFS-INV was significantly improved for zanubrutinib postmatching (**Figure 2A**); OS was potentially improved for zanubrutinib postmatching (**Figure 2B**)
- CR favored zanubrutinib in the unadjusted and base case adjusted populations (**Table 3**)
- Results for the sensitivity analyses were consistent with the base case (**Table 3**)

Table 2. Baseline Characteristics of the Zanubrutinib and Acalabrutinib Populations

Covariates	Acalabrutinib ASCEND (n=155)	Zanubrutinib ALPINE (n=327)	Zanubrutinib ALPINE Postmatching (ESS=184.8)
Age ≥75, %	21.9	22.6	21.9
Male, %	69.7	65.1	69.7
ECOG PS score=0 (vs ≥1), %	37.4	39.9	37.4

OR CR zanubrutinib vs acalabrutinib (95% CI, *P* value)	**2.88 (1.18-7.02, *P*=.0198)**	**2.90 (1.13-7.43, *P*=.0270)**	**2.88 (1.13-7.38, *P*=.0273)**	**2.69 (1.06-6.85, *P*=.0377)**	**2.78 (1.09-7.07, *P*=.0316)**	**2.85 (1.11-7.31, *P*=.0294)**	**2.80 (1.09-7.19, *P*=.0326)**	**3.34 (1.15-9.71, *P*=.0264)**

Bold values indicate *P*<.05.

CONCLUSIONS

- This comprehensive MAIC demonstrated a significant PFS and CR advantage, and potentially improved OS for zanubrutinib compared with acalabrutinib
  - Results were robust across multiple sensitivity analyses
- In a previous publication, Kittai et al presented a MAIC to compare the efficacy and safety of zanubrutinib (ALPINE, aggregate) vs acalabrutinib (ASCEND, IPD) in R/R CLL. Findings showed similar efficacy for zanubrutinib and acalabrutinib (PFS-INV) and different adverse event profiles[7]
  - The efficacy results differ from those presented here because the analysis by Kittai et al had several important limitations, including different follow-ups between ALPINE and ASCEND, lack of any adjustment for COVID-19, and incomplete matching variables (eg, no granularity in geographic regions and number and types of prior therapies)
- While MAICs provide a scientific basis for evaluating hypotheses with regards to treatment efficacy across trials, the gold standard for evaluating evidence of relative efficacy remains randomized controlled trials

LIMITATIONS

- There is a potential for bias resulting from the strong assumption that cross-trial differences can be entirely explained by variables selected for matching
- Independent review committee-assessed PFS was not analyzed in the current MAIC due to unavailability of data in ASCEND and the latest ALPINE data cut-off
- The study did not compare safety for zanubrutinib vs acalabrutinib
  - Safety of a drug is best evaluated via meta-analyses that use all available evidence across all indications
  - A recent meta-analysis of 61 trials involving 6,959 patients who received ibrutinib, ibrutinib ± anti-CD20 antibody, acalabrutinib, and zanubrutinib extensively analyzed the AE profiles of zanubrutinib and acalabrutinib across several indications and reported differences between the 2 treatments[6]
